# 1 Introduction

Given a binary relation  $R$  such that is:

- Reflexive:  $aRa$
- Symmetric:  $aRb \Rightarrow bRa$
- Transitive:  $aRb \wedge bRc \Rightarrow aRc$

we say that  $R$  provides a partition  $\Pi$  of  $A$  into disjoint equivalence classes. That is,  $\Pi = \{A_1, \dots, A_k\}$  is defined as follows:

- $\forall A_i, A_j \in \Pi, A_i \cap A_j = \emptyset \iff A_i \neq A_j$
- $A = \bigcup_{i=1}^k A_i$
- $a \equiv b \iff a, b \in A_i$  for some  $A_i \in \Pi$ .

Such idea was used in Computer Science by Galler and Fisher[GF64] as the **union-find data structure** which is a data structure that stores partition of a set into disjoint sets. In particular **union find** consist of two main operation:

- Find Operation: Given two elements  $a, b \in A$  determine if  $\exists A_i \in \Pi$  s.t  $a, b \in A_i$ .
- Union Operation: Given two elements  $a \in A_i$  and  $b \in A_j$ , *merge*  $A_i$  and  $A_j$ . That is, the result of this operation to the partition  $\Pi$  will be a new partition  $\Pi'$  such that  $\Pi' = (\Pi \setminus \{A_i, A_j\}) \cup (A_i \cup A_j)$ .

## 2 Implementation

From now on we are going to assume that our set  $A$  is defined as  $\{0, \dots, n-1\}$  (and if it is not the case we can use a dictionary to map elements from  $A$  to that range).

### 2.1 Representation of the partition

As every subset defines an equivalence class it is equivalent to represent every  $A_i \subseteq A$  with a single element  $a \in A_i$  which is called the *representative* of  $A_i$  (every other element of  $A_i$  will be related to  $a$  by the properties of the binary relation previously defined). Hence, in our union-find data structure every element will either the representative of a certain subset of  $A$  or it will point to someone who is in the same subset (later on different techniques will be discussed to see which is the best element "to point" and what that means).

A union-find data structure consists of an array  $v[0 : n-1]$  and every element  $i \in A$  will either point to another element  $j \in A$  such that they both belong to the same class (in that case  $v[i] = j$ ) or  $i$  will be the representative of a certain class and it will be marked *specially*.
